More Python for Videogames

Videogames Technology Asignatura transversal

Departamento de Automática

Objectives

- 1. Being able to manipulate files in Python.
- 2. Understand and apply Python serialization (pickles and JSON).3. Being able to handle exceptions.

Bibliography

- The Python Tutorial. Section 7.2: Reading and writing files. (Link)
- The Python Tutorial. Chapter 8: Errors and Exceptions. (Link)

Table of Contents

- Reading and writing files
 - Path
 - Opening files
 - Reading files
 - Writing files
 - Useful methods
 - Examples

- 2. Serialization
 - The pickle module
 - The JSON module
- 3. Exceptions
 - Motivation
 - Definition
 - Handling exceptions
 - Clean-up actions

Reading and writing files Path

Path.

A string that identifies a file in a file system

On **Windows**, the path is denoted by:

path = 'C:\Windows\Temp'

On **Linux**, the path is denoted by:

And it is represented in Python by:

path = 'C:\\Windows\\Temp'

But by also using raw string:

path = r'C:\Windows\Temp'

Reading and writing files

Opening files

All file operations are made through a file object

• First of all: Call the open() function

open()

```
open(filename[, mode])
```

Return: An object file

- filename: String with the file name
- mode: Characters describing how the file will be used
 - r: Reading mode, w: Writing mode, +: Reading/Writing mode.
 - b: Binary mode, a: Appending mode

Always, always, always close the file: f.close()

Reading files (I)

The read() function

```
f.read([size])
```

Return: the specified number of bytes

• size: The number of bytes to be read from the file. Default reads the whole file

```
Option r: Read the entire file (f.read())
>>> f = open("/tmp/file", 'r+')
>>> f.read()
'This is the entire file.\\n'
>>> f.read()
''
>>> f.close()
```

Reading files (II)

```
Option 2: Read a single line (f.readline())
>>> f = open("/tmp/file2", 'r+')
>>> f.readline()
'This is the first line of the file.\n'
>>> f.readline()
'This is the second line of the file\n'
>>> f.readline()
''
>>> f.close()
```

Reading files (III)

```
Option 3: Read lines as list (f.readlines())
>>> f = open("/tmp/file2", 'r+')
>>> f.readlines()
['This is the first line of the file.\n',
'This is the second line of the file\n'l
>>> f.close()
Option 4: Read in a loop
f = open("/tmp/file2", 'r+')
for line in f:
    print(line, end='')
f.close()
```

Writing files (I)

The write() function

```
f.write(string)
```

Return: Number of written bytes

• string: String to write

Example 1: Write a line

```
>>> f = open("/tmp/file", 'w+')
>>> f.write('This is a test\n')
15
>>> f.read()
''
>>> f.close()
```

Writing files (II)

Example 2: Write a number

```
>>> f = open("/tmp/file", 'w+')
>>> f.write(str(42))
2
>>> f.close()
```

Useful methods

Метнор	Description
f.tell()	Returns the pointer's position
f.seek(n)	Moves the pointer n bytes
f.close()	Closes a file. Use it always!

```
>>> f = open("/tmp/file", 'rb+')
>>> f.write(b'0123456789abcdef')
16
>>> f.seek(5)
5
>>> f.read(1)
b'5'
>>> f.close()
```

Example 1

Calculating the average of characters per line of file example.txt

```
file_ex = open('example.txt', 'r')
num_total_char = o
count_line = o

for line in file_ex:
    count_line += I
    num_total_char += len(line)
file_ex.close()
print('average', float(num_total_char) / float(count_line))
```

Reading a line each time

names txt

```
Juan
Laura
Pablo
Enrique
Javier
```

Output

```
1: Juan
2: Laura
3: Pablo
4: Enrique
5: Javier
```

Serialization

The pickle module: Introduction

- What happens if we need to store complex data structures?
 - Think about lists, dictionaries or even objects ...
 - The pickle module comes to help.
- Pickling: Transform an object to string representation.
- Unpickling: Reconstruct an object from its string representation.
- Given an object x and a file object f ...

```
>>> pickle.dump(x, f)
>>> x = pickle.load(f)
```

Serialization

The pickle module: Examples

```
Save a list to a file

import pickle

list_number = [2, 5, 7, 8]

f = open('list.pickle', 'wb')

pickle.dump(list_number, f)

f.close()
```

Load a list from a file

```
import pickle
f = open('list.pickle', 'rb')
list_number = pickle.load(f)
```

print(list number)

The JSON module: Introduction

JSON: JavaScript Object Notation

- Data format for hierarchical data
- Created in 2001 for stateless client-server communication
- Text-based
- Interoperable (pickles only for Python)
- Complex data structures

filename.json

Serialization

```
{
  "firstName": "John",
  "isAlive": true,
  "age": 27,
  "address": {
      "streetAddress": "21 2nd Street",
      "city": "New York",
      "state": "NY",
},
  "phoneNumbers": [ "III", "333"]
}
```

Serialization

The JSON module: Examples

```
Save a list to a file

import json

mylist = ["John", 42, "Smith"]

myfile = open("myfile.json", "w")

json.dump(mylist, myfile, indent = 4)
```

```
Load a list from a file

import json

mylist = json.load(open('myfile.json'))
print(mylist)
```

Motivation

Errors happen

- We need a mechanism to handle errors
- Some errors happen before execution (syntax errors)
- Others are only detected in execution (runtime errors)
 - We need tools to handle errors: Exceptions

```
>>> while True print('Hello world')
File "<stdin>", line 1
    while True print('Hello world')

SyntaxError: invalid syntax
>>> int("hola")
Traceback (most recent call last):
    File "<stdin>", line 1, in <module>
ValueError: invalid literal for int() with base 10: 'hola'
```

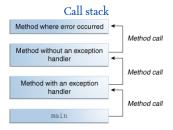

Exception definition (I)

Exception: An error that disrupts the normal execution flow

- File not found, division by zero, invalid argument, etc
- Code cannot be executed
- Elegant solution to handle errors

Exception definition (II)

Call stack: Sequence of invoked methods

Exception definition (III)

Exception handling Throws exception - Method where error occurred Looking for appropriate handler Method without an exception Forwards exception handler Looking for appropriate handler Method with an exception Catches some other exception handler main

When an error happens ...

- Code execution is stopped
- 2. An exception is thrown
- 3. The interpreter goes back in the call stack
- 4. When the interpreter finds an exception handler, it is executed

The exception handler catches the exception, the program finishes otherwise

Exception definition (IV)

```
Traceback (most recent call last):
    File "rzpz.py", line 57, in <module>
        start_simulation (args.scenario)
    File "rzpz.py", line 41, in start_simulation
        u.load_simulation (config)
    File "/home/david/repositorios/rzpz/rzpz/utils.py", line 175,
        in load_simulation
        with open(json_file, 'r') as fp:
FileNotFoundError: [Errno 2] No such file or directory: 'foo.
        json'
```

Handling exceptions (I)

Handling an exception requires a try-except statement

- try: Encloses the vulnerable code
- catch: Code that handles the exception

```
try-catch statement

try:
    # Risky code
except ExceptionType1:
    # Handle error
except ExceptionType2:
    # Handle error
except:
    # Handle error
```

Handling exceptions (II)

```
try-catch example

try:
    x = int(input("Please enter a number: "))
except ValueError:
    print("Oop!, that was not a number!")
except KeyboardInterrupt:
    print("Got Ctrl-C, good bye!")
```

The exception type contains the error

Handling exceptions (III)

```
try-catch example

try:
    f = open('file.txt')
    s = f.readline()
    i = int(s.strip())
texcept IOError as err:
    print("I/O error: " + err)
texcept ValueError:
    print("Could not convert data to integer")
texcept:
    print("Unexpected exception")
raise
```

New Python elements

- Raise
- Exception as object

Clean-up actions

Sometimes we need to execute code under all circumstances

- Typically clean-up actions: Close files, database connections, sockets, etc
- The **finally** clause solves this problem

```
Example

try:
raise KeyboardInterrupt
finally:
print("Goodbye, world!")
```
